ABSTRACT

This report was put together to support the International Atomic Energy Agency (IAEA) REAL-2016 activity to validate the dosimetry community's ability to use a consistent set of activation data and to derive consistent spectral characterizations. The report captures details of integral measurements taken in the Annular Core Research Reactor (ACRR) central cavity with the 44 inch Lead-Boron (LB44) bucket, reference neutron benchmark field. The field is described and an "a priori" calculated neutron spectrum is reported, based on MCNP6 calculations, and a subject matter expert (SME) based covariance matrix is given for this "a priori" spectrum. The results of 31 integral dosimetry measurements in the neutron field are reported.

Key Words: Spectrum Adjustment, Spectrum Unfolding, Reactor Dosimetry

1 FIELD DESCRIPTION

The ACRR is a pulse and steady-state, pool-type research reactor that maintains a large, dry irradiation cavity at the center of its core. The ACRR is typically used to perform irradiation testing where a high neutron fluence is required for a short period of time. Historically, the ACRR has been used for a wide variety of experiment campaigns including electronics damage testing, nuclear fuels testing, space nuclear thermal propulsion testing, and medical isotope production. The ACRR is currently fully operational. The ACRR's main attributes include a large, dry central irradiation cavity, epithermal neutron fluence, and large pulsing capabilities.

Figure 1 shows the ACRR looking into the pool during a 2 MW steady-state power operation. The ACRR core is shown on the left in the figure. The 23.3 cm diameter dry cavity extends from above the pool through the center of the core. The reactor facility also accommodates the fueled ring external cavity-II (FREC-II), shown on the right in the figure, which maintains a larger dry cavity and uses uranium/zirconium-hydride (U-ZrH) TRIGA fuel as a subcritical multiplier. FREC-II provides the user with a larger experimental volume and the fuel arrangement limits the neutron fluence gradient across the test volume.

*Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Figure 1. The ACRR and FREC-II operating at 2-MW steady-state power.

The ACRR maintains an epithermal neutron fluence spectrum in the core and central cavity. This allows for the neutron energy fluence spectrum to be tailored to the desired specifications of an experiment by introducing various spectrum modifying buckets. Moderators can be used within the cavity to thermalize the neutron spectrum. Boron and lead can be used to increase the fast neutron fluence ratio and decrease the gamma-ray fluence, respectively. For an unmoderated condition, the neutron fluence at the center of the central cavity, at the core axial center-line, is $\approx 2.0 \times 10^{13}$ n/cm² per MJ of reactor energy. About 46% of the neutron fluence is above 100 keV and 58% above 10 keV. The 1 MeV damage-equivalent silicon fluence is $\approx 7.6 \times 10^{12}$ n/cm² per MJ of reactor energy. The prompt gamma-ray dose at the same position is $\approx 7.9 \times 10^3$ rad(Si) per MJ. The delayed gamma-ray dose is $\approx 3.4 \times 10^3$ rad(Si) per MJ.

The ACRR can operate in a steady-state, transient, or pulse mode. In the steady-state mode, the operating power level is limited to 4 MW. In the pulse mode, a maximum pulse size of 250 MJ with a full-width half-maximum (FWHM) of 6 ms can be attained. In the transient mode, the reactor power shape can be tailored to the desired requirements for a total reactor energy deposition of 300 MJ. The transient mode can be used to increase the reactor power quickly; for example a ramp increase in power level linear with time from low power to high power. The ACRR is fueled by a 236 element array of UO₂-BeO fuel elements. The fuel is uranium enriched to 35 weight percent ²³⁵U, with 21.5 weight percent UO₂ and 78.5 weight percent BeO. The ACRR fuel elements are stainless steel clad, 3.747 cm in outer diameter and 52.25 cm in fuel length. Within the elements are niobium cups that hold the UO₂BeO fuel pieces. The ACRR is controlled by two fuel-followed safety rods, three poison (void-followed) transient rods, and six fuel-followed control rods. The

control rods make up part of the 236 elements for the normal core configuration. Further information regarding the ACRR can be found in SAND2006-3067 [1].

The purpose of the LB44 bucket is to fit within the 23.3 cm diameter ACRR central cavity and filter out thermal neutrons and gamma rays from the internal experiment volume, producing an epithermal neutron environment with a high neutron-to-gamma ray ratio. This type of environment allows for a high 1-MeV damage equivalent in silicon neutron fluence with a low total dose in silicon. This environment is in high demand by facility experimenters. It is anticipated that more buckets of the LB44 type will be built over the next several years. The LB44 bucket configuration is a relatively new design and was constructed in CY2010. In order to filter out the thermal neutrons, the bucket has an outer annular volume filled with B₄C powder. To filter out the gamma rays, the bucket has an inner Pb annular liner. The bucket also has B₄C and Pb on the bottom so that the bucket can be used at elevated positions within the cavity with the same filter effectiveness. A drawing of the LB44 bucket is shown in Figure 2. The bucket weighs approximately 230 kg and can support an additional experiment payload of up to 114 kg. A thermocouple (TC) fixture can be inserted into the Pb region of the bucket to measure temperature as a function of time at power, thus permitting use during long steady-state irradiations. The bucket can be operated at up to 500 MJ in an un-instrumented (no TC) condition. An unlimited number of maximum pulse operations can be performed on the bucket. The measured reactivity worth of LB44, compared to the free-field condition, is -\$6.07.

This document presents the benchmark data necessary to perform a spectrum adjustment for the ACRR LB44 environment. The designation for this environment is ACRR-LB44-CC-32-cl. The necessary data includes an “a priori” spectrum with associated uncertainties and correlations, and the measured activities of neutron activation foils irradiated in the environment. Table I details the set of spectrum characterization irradiations that were performed in 2011 and 2012 in order to characterize this neutron field for electronics damage testing. When gathering spectrum characterization data, a series of separate reactor operations were used. High purity germanium (HPGe) detectors were used for reading the dosimetry foils. Typically the detectors will yield values for the activity of the same foil that are reproducible to within 1-3%. If detector counts total more than 10⁴ and background counts are low so that statistical uncertainties are small, then the uncertainty of an activity measurement is less than $\approx 5\%$. Cadmium and boron covers were used to alter the region of energy response for some of the activation foils. The boron balls were large enough to alter the neutron field in the surrounding region, so each boron-covered activation foil was exposed on a separate operation. Fission foils were not stacked in the boron ball since previous testing had shown that the neutron scattering between adjacent fission foils thermalized enough neutrons to alter the dosimeter response of ²³⁵U and ²³⁹Pu foils. The ⁵⁸Ni(n,p) reaction was used to normalize the separate reactor operations to a uniform neutron fluence. Hence, every irradiation contained at least one Ni foil for the purpose of normalization.

2 MCNP MODEL OF THE REACTOR ENVIRONMENT

High fidelity calculations were performed to provide the best possible calculated neutron spectrum. This is the spectrum that should be used as input to various spectrum adjustment codes, or as the trial spectrum in iterative unfolding codes. The radiation transport was performed with the continuous energy, three dimensional Monte Carlo particle transport code MCNP [2]. The MCNP model of the ACRR with the LB44 bucket on the 32-inch pedestal is shown in Figure 3. The MCNP input file is included in Appendix A of this document.

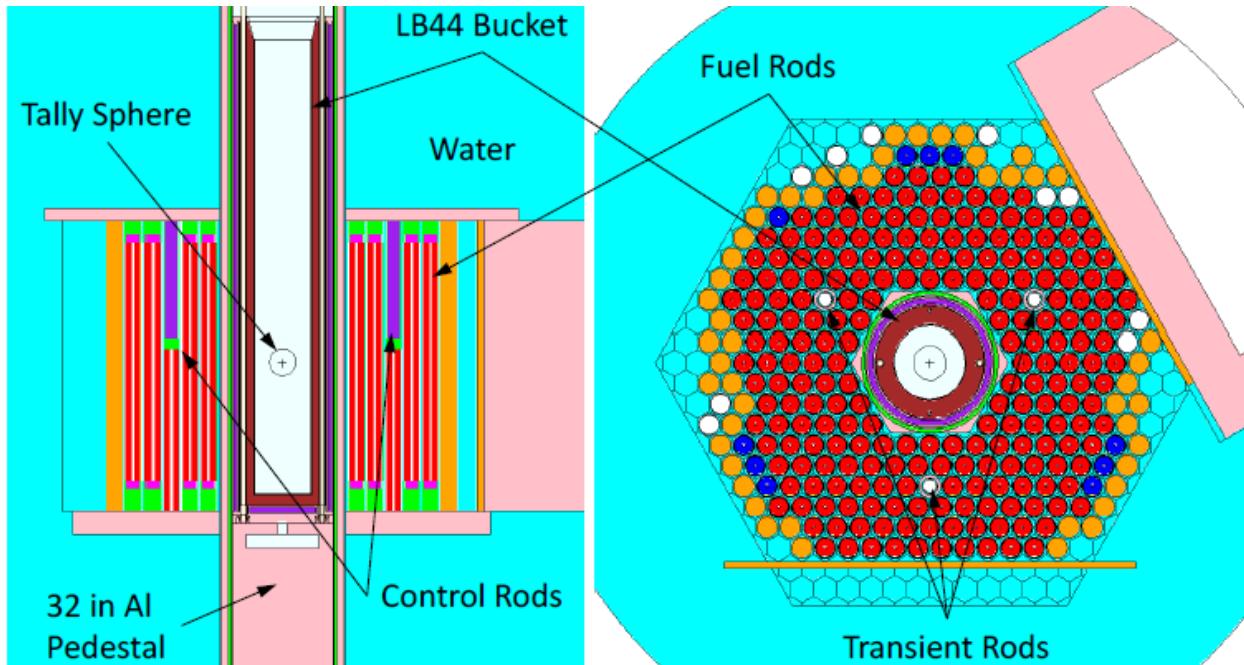

Figure 3. MCNP model of the ACRR and the central cavity with the LB44 bucket on the 32-inch pedestal.

The model does not include the FREC-II. The reason for this is that, although the FREC-II is located within the core tank, the normal operating mode is to have it tilted back and decoupled from the core using a nickel plate. In this position the FREC-II has only a small effect on the neutronic behavior of the ACRR. The MCNP model of the ACRR includes all of the fuel elements and the control, safety, and transient rods that make up the core. The control, safety, and transient rods can be adjusted in the vertical direction in the model to whatever position is desired. Typically, the model is run with the safety and transient rods in the full-out position and the control rods in the full-out, full-in, or delayed critical (dc) position. The calculated dc position can be found for the model by iterating on the control rod position until the multiplication factor is equal to unity.

Neutron, prompt gamma-ray, and delayed gamma-ray energy spectra and fluence per fission were calculated using a 6 cm diameter tally sphere. For the ACRR-LB44-CC-32-cl position, the sphere was positioned at the radial center of the cavity and at the axial center-line of the core. Calculations were performed using the MCNP k-code mode for the neutron and prompt gamma-ray environments, and in the source mode for the delayed gamma-ray environment.

3 CALCULATED TRIAL SPECTRUM

Included in Appendix B is a 640 group representation of the calculated ACRR LB44 neutron spectrum normalized to a fluence of 1 n/cm^2 . The energy grid is the SAND 640 group structure. This spectrum was calculated using the MCNP input model given in Appendix A. The statistical uncertainties in the Monte Carlo calculation were less than 10% for energies between 1.8×10^{-8} MeV and 2×10^{-7} MeV and again between 1.2×10^{-6} MeV and 13.6 MeV. They were less than 1% for energies above 1.2×10^{-5} MeV and below 7.3 MeV. The number fractions in column 5 of the table sum to unity. The differential number spectrum is shown in Figure 4a. These quantities, appearing in column 7 of the spectrum table in Appendix B, when integrated over energy, give unity. Figure 4b shows the differential energy spectrum, also known as a lethargy plot. In a lethargy plot, equal areas under the curve correspond to equal neutron number fractions when plotted with a linear scale for the ordinate and a logarithmic scale for the abscissa.

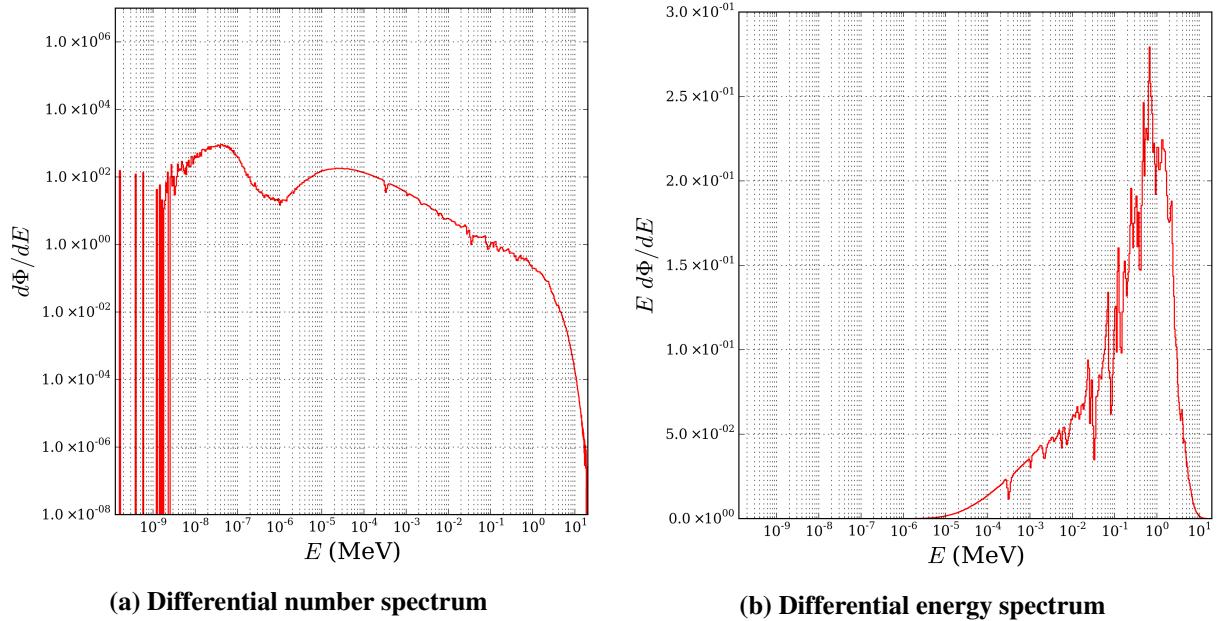

Figure 4. Calculated spectrum in the ACRR LB44 bucket environment.

4 “A PRIORI” SPECTRUM COVARIANCE

An “a priori” spectrum covariance matrix was derived using the methods detailed in reference [3] and subject-matter expertise. The data needed to construct the covariance matrix is given in Appendix C. The representation is consistent with the format used in the LSL-M2 code [4]. To capture the covariance matrix, the number of energy groups is given, followed by the energy bin boundaries, the number fraction representation of the spectrum in this energy group structure, the standard deviations of the “a priori” spectral representation given as relative percentages, and finally an upper triangular representation of the relative correlation matrix. This information is given in Appendix C for an energy group structure containing 89 groups. This 89 group structure is used in the NuGET code [5]. From these inputs a covariance matrix can be constructed. Figure 5 shows the relative correlation matrix indexed by the energy bin number.

The correlation matrix given in Appendix C, which is plotted above is positive definite. 5 MEASURED ACTIVITIES WITH UNCERTAINTIES

Table III lists a set of 31 reactions and associated covers where good measurements were made during this spectral characterization effort. In general, the saturated activity is given in units of Bq per atom of the target isotope or as fissions per atom of the target fissionable isotope. Any special considerations are addressed in the next section. The uncertainty is given as a fractional uncertainty, e.g. an entry of “0.045” means that this activity measurement had an uncertainty of 4.5% due to systematic and random considerations. Uncertainty considerations included the calibration of the energy-dependent HPGe detector, reproducibility of the foil placement on the counter, counting statistics, and the peak fitting algorithm.

6 FOIL COVERS AND SELF-SHIELDING CONSIDERATIONS

The covers used for some of the foils are shown in Figure 6. Included in this figure is the stand that was used to hold the boron balls at the axial core center-line during irradiation. The notation for the covers as indicated in Table III is explained in the following list:

- The configuration notated as “Bare” represents a foil with no cover material, with a thickness between 5 and 10 mils.
- The configuration notated as “Cd” consists of a cylindrical Cadmium cover with an areal thickness of 2.587×10^{-3} atoms/barn.
- The configuration notated as “BB” consists of an inner thick Cadmium cover with an areal thickness of 4.705×10^{-3} atoms/barn and an outer spherical boron ball. The boron ball is a spherical shell with an outer diameter of 4.76 cm and thickness of 1.03 cm. The B₄C has a density of 2.5 g/cm³ with enriched Boron (91.67% ¹⁰B and 8.33% ¹¹B).

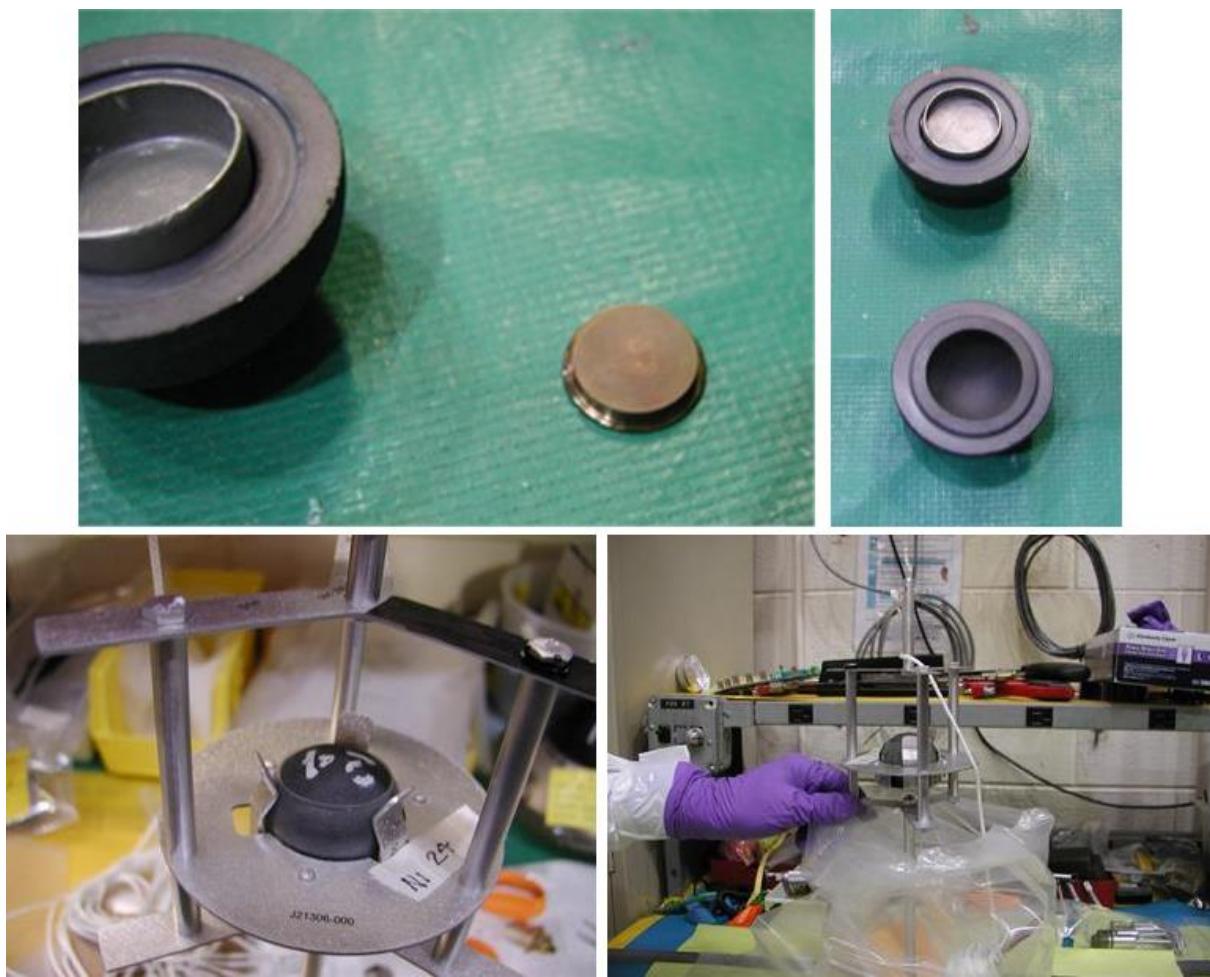

Figure 6. Boron ball and cadmium cover configuration with irradiation stand.

A detailed description of the covers and a discussion of how self-shielding effects are rigorously addressed in Sandia's use of activation measurements to characterize the spectra in our facilities can be found in reference [6]. The energy dependent cover corrections and self-shielding factors are available from the authors in the form of a spreadsheet for each of the reactions listed in Table III.

7 CORRELATION BETWEEN MEASURED ACTIVITIES

At this time there has been no analysis to identify a correlation between activity measurements. While the energy-dependent calibration and the use of the same foil for reading several activity products will introduce some correlation in the uncertainty contributions, the dominant uncertainty contribution is in the counting statistics, peak fitting and the background. The current recommendation is that these activity measurements can be treated as being uncorrelated. Future work at the facility will focus on a better characterization of any correlation between activity measurements.

8 SUMMARY

This report has documented a set of data that can be used as part of the REAL-2016 IAEA-sponsored exercise to examine the consistency of state-of-the-art approaches to spectrum adjustment when applied to the LB44 environment in the ACRR central cavity reference neutron field. Other validation data exists for this benchmark neutron field [7], but this report captures all the field characterization data relevant to this IAEA exercise.
